

Orchid Safety Release Valve™

The Orchid Safety Release Valve™ (SRV) is a sterile, single patient use connector for needle-free access, placed between the existing IV extension set and general IV tubing connection intended to be used for delivery of fluid to/from an IV catheter. The Orchid SRV can be used during direct injection, intermittent infusion, and continuous infusion.

Dislodgement is most frequently caused by patient confusion or removal of the catheter, loose dressing or tape, or tubing tangled in the bed or linens.¹

Helping to Solve a Major Issue

Of the 342 million peripheral IVs in the U.S. each year², up to 10% may dislodge³, costing over \$2 billion annually. The Orchid SRV addresses this issue by reducing dislodgement, improving patient satisfaction, and freeing clinicians from some unnecessary restarts.

stabilization

How the Safety Release Valve Works

When tension on the IV line activates the SRV, the valve disconnects and seals off both sides of the IV creating a sterile barrier. The clinician restores the line by simply removing the separated halves and replacing them with a new, prepackaged, sterile valve.

IV ADMINISTRATION SET

The valve attaches to the administration set using a standard luer connector, making it easy to integrate with existing IV's.

ORCHID SRV

The single-use valve prevents post-dislodgement reconnection. It utilizes a latex-free, MRI-compatible seal and proprietary design to enclose the flow path.

IV EXTENSION SET

As with the IV administration set, the SRV attaches to the extension set using a standard luer connector.
